<b>COMPUTING SUBJECT:</b>	Secure Socket layer
TYPE:	Assignment
<b>IDENTIFICATION:</b>	Secure SocketC#
COPYRIGHT:	Michael Claudius
LEVEL:	Medium
TIME CONSUMPTION:	2-4 hours
EXTENT:	50 lines
<b>OBJECTIVE:</b>	SSL sockets in practice
PRECONDITIONS:	X509 No. 2, socket exercises Computer Networking Ch. 8.5

**COMMANDS:** 

## **IDENTIFICATION:** SecureSocketC/MC

## The Mission

You are to make a secure connection communication by setting up a server and a client using the secure socket layer (SSL) by sharing the certificate provided by the server. This we shall do in three steps/assignments:

- 1. CertificateX509, Install Windows SDK and investigate the tools makecert and pvk2pfx
- 2. CreateCertificateX509, Create self-signed X509 Root and Server SSL certificates
- 3. Secure SocketsC#, Use the certificates and SslStream for secure socket communication

You have already done the first two assignments and this assignment is the Assignment No.3.

## <u>Purpose</u>

The purpose of this assignment is to use the previously created certificates in server and client programs with SslStream class to achieve secure socket communication.

When surfing on the net it is easy to find many descriptions more or less useful, and in more or less updated versions. Here are some:

## Useful links for for C#-programs with SSL

http://msdn.microsoft.com/en-us/library/system.net.security.sslstream(v=vs.110).aspx

http://msdn.microsoft.com/en-us/library/ms145056(v=vs.110).aspx

http://www.dib0.nl/code/367-using-a-client-certificate-with-an-ssl-stream-in-c

Useful links for for Java-programs with SSL

Keytool - Key and Certificate Management Tool Solaris Programmers tool to create keys

<u>Keytool – Key and Certificate Management Tool</u> Windows Programmers tool to create keys in Java

Local server and client on one computer
 First download the project TCPEchoServerX with the normal TCPEchoServer & TCPEchoClient from your teacher's homepage.
 Run the TCPEchoServer and TCPEchoClient.
 Type something in the client window.
 Test the communication.

2. Server and client on two different computers

This assignment is best performed by small group of students on the wireless local DMU LAN network or set up a hotspot on your using a shared mobile.

Lookup the IP address of the server computer. (eg. Click: start -> run -> cmd -> 'type ipconfig'). Start the TCPEchoServer on one computer.

On another computer modify the TCPEchoClient to create a socket to the server (your partner) ie. change "localhost" to the IP-address of the server.

Start the WireShark (a third partner) (i.e. start -> capture -> interface -> open)

Run the client and start to communicate.

Stop WireShark and view the captured packets.

You should now be able to read the packet content given as plain text.

You are now to change the echo-application to use Secure Socket Layer (SSL).

3. Use of SSL stream in the server on one computer You can be inspired by the link:

http://msdn.microsoft.com/en-us/library/system.net.security.sslstream(v=vs.110).aspx

Or just use the instructions given below.

Copys the TCPEchoServer to a new program and then modify it to utilize a secure stream instead of the normal network stream (named: ns, unsecureStream or something like this) by extending the main().

In the start of main add the following definitions

Be sure you understand the classes SslProtocols and X509Certificate. Investigate !

Then change/extend the program with the following declarations:

Be sure you understand the classes SslSteam and the method AuthenticateAsServer. Investigate !

Finally change the program to use sslStream instead of unsecureStream in the rest of the program. Compile and run. Then run the client.

This is of course not working as the client is not using SSL as required by the server.

4. Use of SSL stream in the client on one computer You can be inspired by the link:

http://msdn.microsoft.com/en-us/library/ms145056(v=vs.110).aspx

Or just use the instructions given below.

Copy TCPEchoClient to a new file and then modify the program to utilize a secure stream instead of the normal network stream (named: ns, unsecureStream or something like this) by extending the main().

In the start of main add the following definitions:

```
string certificateServerName = "FakeServerName";
Stream unsecureStream = connectionSocket.GetStream();
bool leaveInnerStreamOpen = false;
SslStram sslStream = new SslStream(unsecureStream, leaveInnerStreamOpen);
sslStream.AuthenticateAsClient(certificateServerName);
```

where the certificateServerName is the subject certificate name you used when creating certificates like "FakeServerName" or whatever you choose.

Remember to utilize sslStream in the rest of the program. Run the server and client again.

6. Secure server and client on two different computers

Follow the instructions in Assignment 2 but now for the SSL based TCPEchoServer and TCPEchoclient.

Remember that the sender and receiver must trust each other; i.e. one must install the others Root and server certificate.

Hopefully you now cannot see the plain text but only cipher text!

7. Extra assignment for the fast ones. Not that easy Copy and paste the application into a new application Then change the server and client programs to use validation of the client. *Tip: Client should have a X509 certificate. Tip: The server must validate the client. The client must validate the server.* 

*Extra tip:* RemoteCertificateValidationCallback and CertificateSelectionCallback
